Week 4 - Sorting and Searching Algorithms

This lab sheet will introduce two algorithms from computer science. After this session you will be able to sort and search lists using the two following algorithms:

- Insertion and Bubble sort algorithm;
- Binary search.

Sorting Algorithms

1. **TICKABLE** The following code create a list of digits from 1 to 31.

   ```
   l = range(1, 31)
   print l
   ```

   If we import the random library we can pick a random sample of the list and **shuffle** this it (do not worry too much about this):

   ```
   import random
   jumbledlist = random.sample(range(1, 31), 20)
   random.shuffle(jumbledlist)
   print jumbledlist
   ```

   Using pen and paper, sort the above list, attempting to understand a general approach to doing this. Write a function **jumbledlist** that takes as arguments: **maximumnumber** and **sizeoflist** which returns a jumbled list of integersas above.

2. **TICKABLE** Python has a built in method on lists to sort them: **sort()**:

   ```
   l = jumbledlist(30, 20) # Use the function you created above.
   print l
   l.sort()
   print l
   ```

   In this question we will take a look at one type of algorithm that can be used to sort a list: "Selection sort".

   The main idea behind this algorithm is to create a new (empty at first) list and go through the old list and slowly pick out the 'next' element to go in the new list.

   Here is some **pseudo code** that describes this:
Figure 1:

```
INITIATE NEWLIST
WHILE MORE ELEMENTS IN NEWLIST THAN IN OLDLIST:
    FIND SMALLEST ELEMENT IN OLDLIST
    MOVE THAT ELEMENT TO NEWLIST
```

It should be straightforward to see that at every step of this algorithm we the total size of NEWLIST and OLDLIST stay the same. As such we can simply put the NEWLIST at the beginning of the OLDLIST so that at each step of our algorithm we are basically moving elements from the unsorted part of the list to the sorted part of the list.

Here is some **pseudo code** that describes the 'insertion sort' algorithm:

```
SET FIRSTUNSORTED TO 0
WHILE NOT SORTED:
    FIND SMALLEST UNSORTED ITEM
    SWAP FIRST UNSORTED ITEM WITH EARLIEST UNSORTED ITEM
    SET FIRSTUNSORTED TO FIRSTUNSORTED + 1
```

Here is some python code that carries out the above algorithm, experiment with it and include comments:

```python
def insertionsort(data):
    firstunsorted = 0
    while firstUnsorted < len(data) - 1:
        indexOfSmallest = firstUnsorted
        index = firstUnsorted + 1
        while index <= len(data) - 1:
            if data[index] < data[indexOfSmallest]:
                indexOfSmallest = index
            index += 1
        data[firstUnsorted], data[indexOfSmallest] = data[indexOfSmallest], data[firstU
        firstUnsorted += 1
```
Figure 2:

3. There are various other algorithms that can be used to sort lists. The following pseudo code is for an algorithm called 'bubble sort'. Attempt to write out the corresponding python code:

```
SET FIRSTUNSORTED TO 0
SET SWAP TO TRUE
WHILE FIRSTUNSORTED < LENGTH - 1 AND SWAP:
    SET SWAP TO FALSE
    "BUBBLE UP" THE SMALLEST ITEM IN AN UNSORTED LIST
    SET FIRSTUNSORTED TO FIRSTUNSORTED + 1
```

Here's the pseudo code for the "BUBBLE UP" part of the above code:

```
SET INDEX TO LENGTH - 1
WHILE INDEX >  FIRSTUNSORTED + 1:
    IF DATA[INDEX] < DATA[INDEX - 1]
        SWAP DATA[INDEX] AND DATA[INDEX - 1]
        SET SWAP TO TRUE
    SET INDEX TO INDEX - 1
```

4. The 'time' module allows you to get the current system time on your machine:

```
import time
print time.time()
```

Using this we can write a function that will evaluate how long it takes to run a particular function:

```
timing(string):
    starttime = time.time()
    eval(string)
    return time.time() - starttime
```

This uses the `eval` function which runs any string of code. We can define the following test function:

```
def testfunction():
    return 10 ** 1000
```

We see how long a single run of this testfunction takes using our timing function:

```
print timing("testfunction")
```

Modify the timing function so that it returns the average time taken over 10 evaluations of the passed code. Furthermore use this function to evaluate the performance of the bubble sort and insertion sort algorithms.

(Note that python also has a timeit library which offers timing functionality.)

Searching algorithms

5. **TICKABLE** Search a list by hand.

6. **TICKABLE** Code for iterative binary search.

7. Code for recursive binary search.
